Abstract

Approval of hierarchy and inequality in society indexed by social dominance orientation (SDO) extends to support for human dominance over the natural world. We tested this negative association between SDO and environmentalism and the validity of the new Short Social Dominance Orientation Scale in two cross-cultural samples of students ($N = 4,163$, $k = 25$) and the general

population ($N = 1,237$, $k = 10$). As expected, the higher people were on SDO, the less likely they were to engage in environmental citizenship actions, pro-environmental behaviors and to donate to an environmental organization. Multilevel moderation results showed that the SDO–environmentalism relation was stronger in societies with marked societal inequality, lack of societal development, and environmental standards. The results highlight the interplay between individual psychological orientations and social context, as well as the view of nature subscribed to by those high in SDO.

Keywords

social dominance orientation, environmentalism, social context, cross-cultural research

Psychological science has been contributing to the quest of solving environmental problems by identifying key contextual and individual factors that promote pro-environmental actions (for reviews, see Clayton, 2012; Gifford, 2014). These have included normative aspects of the local and the societal context (e.g., Milfont & Markowitz, 2016; Schultz, Bator, Tabanico, Bruni, & Large, 2013) as well as individual differences in personality and values (e.g., Evans et al., 2013; Milfont & Sibley, 2012). One barrier in attempts to promote pro-environmental actions is the pervading belief in human dominance over nature (Pirages & Ehrlich, 1974; White, 1967). The present article investigates this issue and contributes to an emerging line of research examining whether our acceptance of hierarchy and inequality in the social world extends to acceptance of hierarchy in the natural world, with humans placed above non-humans (e.g., Milfont, Richter, Sibley, Wilson, & Fischer, 2013).

One of the most commonly used ways of conceptualizing the need to dominate is social dominance orientation (SDO) which assesses the degree to which an individual approves group-based hierarchies and inequalities (Pratto, Sidanius, Stallworth, & Malle, 1994; Sidanius & Pratto, 1999). SDO is one of the most widely used variables in social and personality psychology, and it has been shown to predict a wide variety of intergroup attitudes and behaviors (see Kteily, Ho, & Sidanius, 2012; Lee, Pratto, & Johnson, 2011). Notably, research indicates that this enduring preference toward hierarchy and inequality not only predicts group-relevant variables but also relates to environmentalism. In one of the first articles describing SDO, Pratto et al. (1994) showed across three samples that individuals scoring higher on SDO were less supportive of environmental policies than individuals scoring lower on SDO, and this negative association remained strong after controlling for political-economic conservatism.

The negative association between SDO and environment-relevant variables has been confirmed in several more recent publications. SDO has been shown to relate to priority given to business gains over environmental protection (Son Hing, Bobocel, Zanna, & McBride, 2007), support for utilitarian attitudes toward nature (Milfont & Duckitt, 2010), opposition to protecting nature (Milfont et al., 2013), support for environmental inequality (Jackson, Bitacola, Janes, & Esses, 2013), denial of anthropogenic climate change (Häkkinen & Akrami, 2014; Milfont et al., 2013), greater beliefs that humans are distinct from and superior to animals (Dhont, Hodson, Costello, & MacInnis, 2014), and more meat consumption (Allen, Wilson,

Ng, & Dunne, 2000). In conjunction, these findings indicate that preference for group-based hierarchies and inequalities translates into preference for hierarchy in the natural world, with humans dominating nonhumans.

We note, however, that despite the robustness of the negative association between SDO and environmentalism, most previous research relied on largely Western, single-country studies with single (and often broad) environmentalism measures. Only two previous studies have examined the SDO–environmentalism relation across cultural groups—one examining data from Brazil and Sweden (Jylhä, Cantal, Akrami, & Milfont, 2016) and the other examining the SDO–environmentalism relation at the country level of analysis (Milfont et al., 2013, Study 2). This highlights a need for a better understanding of how our relationship with nature is influenced by the interplay between the personal desire to dominate and the societal context within which the individual resides, especially because SDO varies within cultural and institutional contexts (Fischer, Hanke, & Sibley, 2012). In this article, we expand on this research by conducting the first large-scale study examining the association between SDO and three distinct behaviors related to climate change mitigation across 25 countries. We use multilevel analysis that allows the proper examination of the correlation between SDO and environmentalism at the individual-level of analysis while also examining whether country-level indicators may influence that correlation.

Particularly, we test robustness and moderation hypotheses following Pratto et al. (2013). According to the robustness hypothesis, we expect that SDO will correlate negatively with environmentalism for participants in all 25 countries included in our study. At the same time, societal contexts may reinforce or weaken the belief in human dominance over nature. Even if the negative association between SDO and environmentalism is observed consistently across nations, this association may be strongest where contextual factors reinforce the dominating role of humans as the master of nature. We thus expand the individual-level analysis by examining whether nation-level variables influence the SDO–environmentalism relation (i.e., cross-level interactions). According to the moderation hypothesis, we expect the strength of the negative association between SDO and environmentalism to be moderated by contextual factors that vary across countries.

We focus on three national moderators that may reinforce individual views of human dominance over nature. First, the association between SDO and environment-relevant variables

seems to express issues of inequality in the relations between humans and the natural environment. Moreover, unequal access to resources at the national level may reinforce a competitive, dog-eat-dog mentality that in return legitimizes the exploitation of resources and unequal relations between humans and the natural environment. We therefore expect that levels of inequality in a given nation could strengthen the SDO–environmentalism relation, and selected the Gini index as a measure of equality at the level of nations. Second, prior work has shown that national affluence is associated with greater concern for the environment (e.g., Frazin & Vogl, 2013) and that a nation's wealth strengthens the relationship between a person's beliefs in climate change and their environmental actions (e.g., Bain et al., 2016). We therefore expect that levels of affluence in a given nation could strengthen the SDO–environmentalism relation. We selected the Human Development Index (HDI) as it serves as a parsimonious indicator of affluence and standard of living in a country—including life expectancy, educational attainment, and income per capita indicators—and because HDI has been shown to moderate associations between environment-relevant variables (Liu & Sibley, 2012; Milfont & Markowitz, 2016). Finally, in countries that perform poorly in protecting the environment institutions may work to maintain the current system by justifying a status quo in which the environment is degrading, which in turn may lead to greater internalization of a belief in human dominance over nature. We therefore expect that levels of environmental performance in a given nation could strengthen the SDO–environmentalism relation and selected the Environmental Performance Index (EPI) as a measure of how well nations perform on environmental issues.

To provide a stronger test for these hypotheses, we considered three conceptually distinct environmentalism measures (Stern, 2000) related to climate change mitigation: public and political actions, personal domestic actions, and an economic action (donation to a pro-environmental organization). Moreover, we considered two distinct cross-cultural samples: students ($N = 4,163$, $k = 25$) and the general population ($N = 1,237$, $k = 10$). We also used the opportunity to provide further empirical evidence for the psychometric properties of the 4-item Short Social Dominance Orientation (SSDO) Scale, which previously showed good internal reliability and predictive validity across 20 countries and 15 languages (see Pratto et al., 2013). We tested the psychometric properties and measurement invariance of the SSDO in both samples, across 25 countries and 16 languages, of which 13 countries and 9 languages were not studied by Pratto et al. (2013).

Method

Country and Participants

Data were collected as part of the *Collective Futures and Climate Change* research project (see Bain et al., 2016). The project coordinators (first three authors) developed the project and recruited an international research team. The countries were selected a priori based on a combination of environmental indicators and

geographic region. The goal was to employ convenience sampling to obtain student and nonstudent samples from each country where viable (target $N = 200$ for each sample). Data were obtained from university students across 25 countries spanning all inhabited continents, plus community samples in 10 countries to establish the generalizability and robustness of findings.

Participants completed surveys online in most countries, using a template developed by the authors to maximize consistency in data collection. In Sweden and Israel, contributors developed their own online versions using the same survey template. Where online administration was impractical (Ghana, Japan, Mexico, Poland, South Africa, South Korea, Venezuela), participants completed a paper-based version of the survey that matched the format of the online survey.

All participants first indicated their beliefs about the reality and importance of climate change. The analyses reported in the present study considered only participants who believed climate change is real to have a more homogenous sample and due to low sample sizes of participants unconvinced that climate change is real in many countries. Table 1 provides an overview of the student and community samples in each country.

Questionnaire Translation

For non-English languages, translation-back-translation was completed by competent bilingual speakers or parallel translation where multiple bilingual speakers independently translated the survey. Research coordinators worked with translators until an acceptable translation was agreed upon. All surveys were completed in the major local language. In Ghana and South Africa, the common language of student instruction was used (i.e., English in Ghana; English or Afrikaans in South Africa), and in Switzerland, participants could choose to complete the survey in either German or French.

Measures

The larger *Collective Futures and Climate Change* study included several validated measures (see Supplemental Material). The relevant measures for the present study are described below.

SDO. We used the SSDO Scale (Pratto et al., 2013). This is a 4-item SDO measure with the following instruction: “There are many kinds of groups in the world: men and women, ethnic and religious groups, nationalities, political factions. How much do you support or oppose these ideas about groups in general?” This is followed by the four items: “In setting priorities, we must consider all groups” (reversed), “We should not push for group equality,” “Group equality should be our ideal” (reversed), and “Superior groups should dominate inferior groups.” Items were rated on a 10-point scale ranging from 1 (*extremely oppose*) to 10 (*extremely favor*). The SSDO score was computed by averaging over items after reverse coding relevant items. We used the SSDO translations reported by Pratto et al. (2013), and created new versions in nine additional languages (see Appendix A in Supplemental Material).

Venezuela	179	Spanish	41.9 (12.9)	64

Environmental citizenship intentions. A 12-item measure was used to access participants' intentions regarding environmental citizenship, adapted from Stern, Dietz, Abel, Guagnano, and Kalof (1999). Example items are: "Sign a petition in support of protecting the environment," "Join or renew membership of an environmental group," and "Post pro-environmental messages or links on social media (e.g., Facebook, Twitter)." Items were rated on a 5-point scale ranging from 1 (*not at all likely*) to 5 (*very likely*), as well as "na" (*not applicable*) option. Missing and "not applicable" responses were excluded, and the mean of all remaining items was computed.

Private sphere behavioral intentions. A 12-item measure was used to access participants' intentions to engage in pro-environmental behaviors. Examples of the behaviors included: "Buy environmentally friendly products," "Install products to save energy

(e.g., low-energy light bulbs)," "Reduce car travel (e.g., walk, cycle, use public transport)," and "Avoid or reduce eating meat." Items were rated on a 5-points scale ranging from 1 (*not at all likely*) to 5 (*very likely*), as well as "na" (*not applicable*), with missing and "not applicable" responses excluded before computing the scale mean score.

Donation behavior. In addition to the behavioral intention measures, one question examined participants' donation behavior. Participants were given the instruction:

Each person participating in this survey is eligible to enter a draw for [local currency equivalent of USD150, adjusted to nearest round number] Amazon Gift Card. If you win the prize draw, we would like to know if you would commit to donating some or all of this prize to an environmental organization. If you wish to nominate an environmental organization for your donation, please do so here: [space to enter name of environmental organization]. If you do not nominate an environmental organization, we will send the donation amount you nominated to an international not-for-profit environmental organization.

We used the proportion of the amount participants indicated authorizing the researchers to donate on their behalf if they won.

Nation Variables

We examined whether three nation-level variables would moderate the SDO–environmentalism relation. The figures for the Gini index and HDI were taken from the 2015 United Nations Human Development Report (see Tables 1 and 3 in the statistical annex of that report). The Gini data were not available for New Zealand and South Korea, so we used the most recent Gini data available for these countries from The World Factbook published by the Central Intelligence Agency of the United States. The 2010 EPI was obtained from the website of the Center for International Earth Science Information Network at Columbia University. Greater values for the Gini index, HDI, and EPI indicate more inequality, more human development, and greater environmental performance in the country, respectively.

Results

Rejection of Dominance and Reliability of the SSDO Scale

The mean scores on the SSDO were below the scale middle point of 5.5 across all student and community samples (see Tables 2 and 3), but all samples had participants with ratings above the midpoint (except for the Icelandic community sample). Most distributions were positively skewed, apart from four student samples (China, Germany, Japan, and the Netherlands) and two community samples (Australia and China). Finally, the mean scores on the SSDO were comparable for the student ($M = 3.17$, $SD = 1.65$; $N = 4163$) and community ($M = 3.17$, $SD = 1.68$; $N = 1237$) samples. These results parallel

Note. MIC = mean inter-item correlation. Citizenship refers to public/political behaviors, personal to domestic behaviors, and donation to financial behavior. The SSDO Scale was rated from 1 to 10. Item 2 for Poland had to be recoded as the Polish translation of this item was anti-SSDO.

* $p < .05$. ** $p < .01$. *** $p < .001$.

those reported by Pratto et al. (2013), and overall suggest that participants tended to reject a dominance orientation and that the normativity of this dominance rejection was similar across our student and community samples, but with substantial variability within and across countries.

We conducted a meta-analysis of the Cronbach's α reported in Table 2 using the approach developed by Rodriguez and Maeda (2006). The weighted average α for the student sample was .68 (95% confidence interval [CI] = [.66, .70]), with significant heterogeneity in internal reliability across countries, $Q(24) = 212.81$, $p < .001$. Similar results were observed for the community sample, with a weighted average α of .67 (95% CI [.64, .70]) and significant heterogeneity across countries, $Q(9) = 74.89$, $p < .001$. These results are comparable to those reported by Pratto et al. (2013) and indicate good internal reliability for the SSDO despite the low number of items in the scale.

Measurement Invariance

As an initial indication of the comparability of the one-factor structure of the SSDO scale in each country, we ran factorial procrustean target rotation using values taken from a principal-components analysis of the overall sample as the norm. As shown in Tables 2 and 3, Tucker's Phi—an index of similarity between factor structures across samples—were above the recommended value of .95 (van de Vijver & Leung, 1997), except for one student sample (Japan) and one community sample (China). This supports the conclusion that the one-factor structure was similar across almost all samples.

Besides factor structure comparability, measurement invariance is a prerequisite when comparing groups on a measured construct. When measurement invariance is demonstrated, we can be certain that participants across all groups interpret the items and the underlying construct in the same way, and group comparisons are then meaningful. We assessed the

measurement invariance of SSDO using the alignment approach in Mplus (Asparouhov & Muthén, 2014; see Supplemental Material for details).

The alignment results indicated convergence issues for three countries from the student samples (Brazil, China and Japan) and two countries from the community samples (China and Iceland). These countries were removed from the final alignment model, and results for these countries should be interpreted with caution. Importantly, the alignment results indicated that all items of the SSDO showed invariant measurement loadings for all the remaining countries, and that the SSDO items also showed invariant measurement intercepts in most countries. Given that all four items loaded on the SSDO factor and that the measurement loadings of all items show no indication of measurement noninvariance (except for item SSDO4 for the community sample in Brazil), the results support configural and metric invariance of the SSDO across countries.¹

Testing Robustness and Moderation Hypotheses

We expected that people with higher levels of SDO would be less willing to engage in pro-environmental actions (robustness hypothesis), but this effect was not expected to occur to the same extent across all countries (moderation hypothesis). We calculated the correlations between SSDO and the three environmentalism measures for each country, and then calculated a meta-analytical summary of the correlations. The meta-analyses were performed using an Excel program developed by Piers Steel (University of Calgary) that runs the Schmidt–Hunter method with a random-effects model. It computes the average correlation across all samples weighted by sample size,

with a 95% CI indicating the likely range of this correlation, and a Q-statistic indicating whether the magnitude of the correlations varies substantially across samples. We report the random-effects weighted means when correcting or not for measurement error.

Tables 2 and 3 present the correlations for each country and sample, with the meta-analytical results at the bottom of each table. The results show that, overall, SDO was negatively correlated with all three climate change mitigation measures across both student and community samples, with corrected weighted correlations in the –.17 to –.26 range. Additional analyses confirmed the linear assumption in the SDO–environmentalism relation (see Supplemental Material). Correlations between SDO and environmental citizenship varied significantly across countries for student and community samples; however, correlations between SDO and private sphere behaviors varied significantly across countries only for the student samples, and correlations with donation behavior did not vary significantly across countries (see significance of Q-statistic in these tables and Supplemental Material).

For the measures that showed significant variation across countries (environmental citizenship and private sphere behavior), we used multilevel modeling to explore the reasons for variation. We first analyzed data from the student samples and ran multilevel models examining the extent to which the selected country-level indicators (Gini, HDI, and EPI) would account for the variability in the associations between SSDO and environmental citizenship and private sphere behavior. Multilevel models were run in HLM (student version 7) with restricted maximum likelihood estimation, allowing the slopes to vary across countries, and robust standard errors for

Note. SDO = social dominance orientation. $N = 3,752$, $k = 25$. Political orientation was measured with a 7-point scale ranging from 1 (*very liberal*) to 7 (*very conservative*). Reported results are for the final estimation of fixed effects with robust standard errors ($df = 23$).

* $p < .05$. ** $p < .01$. *** $p < .001$. † $p < .08$.

the final estimation. We used group-mean centering for level-1 variables and grand-mean centering for level-2 variables. Since age, sex, and conservative political orientation are related to SDO, environmentalism or both, we included these variables as covariates at level-1.

We first ran separate multilevel (random-intercepts) models with each of the two environmentalism measures regressed onto SDO. Replicating the meta-analytical findings, SDO was reliably related to environmental citizenship, $\gamma = -.090$, $SE = .014$, $t(24) = 6.55$, $p < .001$ and private sphere behavior, $\gamma = -.080$, $SE = .010$, $t(24) = 7.62$, $p < .001$. In line with the moderation hypothesis, the strength of the associations varied across countries for environmental citizenship, $u = .0030$, $\chi^2(24) = 54.92$, $p < .001$, and private sphere behavior, $u = .0011$, $\chi^2(24) = 41.61$, $p = .014$.

We then added the level-1 covariates in conjunction with the level-2 predictors (Gini, HDI, and EPI, one at a time) to test for cross-level interactions (random-intercepts-and-slopes models). The models were run for each pro-environmental measure separately and comprised the level-1 predictors (SDO, age, sex, and political orientation) plus the interaction terms between these level-1 predictors and the targeted level-2 moderator. The results in Tables 4 to 6 revealed independent main effects for age and sex for both measures, indicating that older people and women were more likely to act pro-environmentally. The main effect for conservative political orientation was only statistically significant for environmental citizenship, but the

direction of the coefficients for both measures indicate that liberals were more likely to act pro-environmentally.

More importantly, the results showed that the level-2 predictors reliably moderated the associations between SDO and the environmentalism measures. Cross-national differences in inequality (indexed by the Gini coefficient) influenced the association between SDO and environmental citizenship ($\gamma = .0030$, $t = 3.09$, $p = .046$) and private sphere behavior ($\gamma = .0022$, $t = 2.24$, $p = .035$). Cross-national differences in human development influenced the association between SDO and environmental citizenship ($\gamma = -.288$, $t = 2.88$, $p = .008$) and private sphere behavior ($\gamma = -.170$, $t = 2.50$, $p = .020$). Cross-national differences in environmental performance influenced the association between SDO and environmental citizenship ($\gamma = -.0035$, $t = 4.34$, $p < .001$) and private sphere behavior (albeit marginally: $\gamma = -.0020$, $t = 1.79$, $p = .086$). The results were statistically nonsignificant for the community samples (perhaps because there were too few countries), but the cross-level interactions showed the same pattern of associations (see Table S5).

Overall, and framing the moderating results on a positive way, the *lower* participants' SDO, the *more* they engage in pro-environmental actions, and this association was stronger in societies that are more equal, with better human development indicators, and with better performance on environmental issues. Although the level-2 predictors are correlated,² the results indicate that HDI has a stronger moderating effect on the

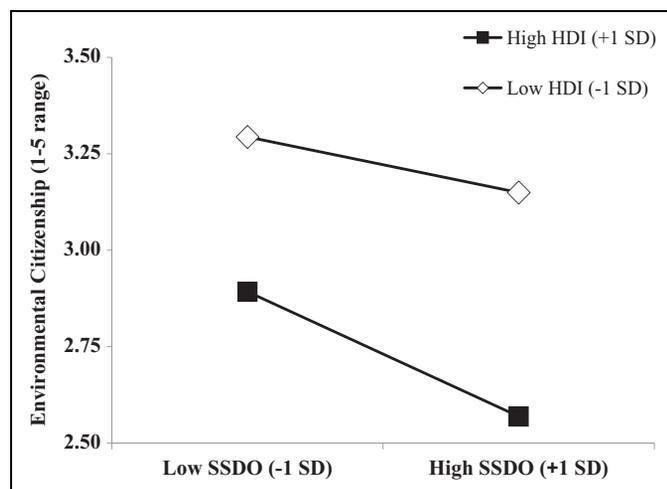

Figure 1. Slopes for the association between social dominance orientation (SDO) and environmental citizenship for the student samples ($N = 3,752$, $k = 25$) at difference levels of country-level standard of living as indexed by the 2015 Human Development Index (HDI). Simple slopes analysis confirmed that the association between SDO and environmental citizenship is stronger (steeper slope) at higher levels of HDI ($\gamma = -.10$, $t = 5.52$, $p < .001$) than at lower levels ($\gamma = -.04$, $t = 2.39$, $p = .025$). The lowest levels of environmental citizenship occur in individuals who reported high SDO and live in countries with high levels of HDI. Portraying the moderation on a positive light, the lower participants' scores on the short social dominance orientation (SSDO) scale, the more they engage in environmental citizenship actions, and this effect is stronger in nations with better human development indicators.

SDO–environmentalism relation. Figure 1 illustrates such moderating effect (see Supplemental Material for further information).

Discussion

SDO indexes an individual's preference for group-based inequality and hierarchy, which has been shown to predict a range of intergroup attitudes and behavior as well as environment-relevant variables. We use multilevel modeling to present the first large scale cross-nation study examining the extent to which the SDO–environmentalism relation is robust across individuals from 25 countries (robustness hypothesis), and whether country-level factors would strengthen or weaken this relation (moderation hypothesis). We tested these hypotheses with the 4-item SSDO Scale, which showed good psychometric properties and measurement invariance in our samples.

Robustness of the SDO–Environmentalism Relation

Our results confirmed that SDO is a reliable negative predictor of environment-relevant variables. Individuals with higher levels of SDO were less likely to engage in environmental citizenship actions, such as signing a petition in support of protecting the environment, boycotting companies that are not environmentally friendly, or communicating pro-environmental messages to others. Likewise, high-SDO individuals were less likely to engage in private sphere behaviors aimed to reduce energy

consumption and negative environmental impacts, and were less likely to donate to an environmental organization.

That SDO was reliably negatively related to all three environmentalism measures and across student and community samples provides strong support for the important role of this individual difference variable for understanding environmental problems. The basic motivation to achieve and maintain hierarchical social structures indexed by SDO helps explain hierarchical relations between humans and the natural environment. Theoretically, this confirms a link between support for social inequality among social groups and support for legitimizing myths justifying human dominance over nature, especially when environmental exploitation helps sustain and widen the gap between dominant and disadvantaged groups in society (Milfont & Sibley, 2014).

At the same time, it is important to note that the effect sizes for the associations between SDO and environment-relevant variables observed in the present study (as well as in others) were relatively small (in the range of $-.17$ to $-.26$ when correcting for reliabilities) when compared to meta-analytical correlations observed between SSDO and attitudes toward minorities—endorsing more women in leadership positions ($-.31$), protecting ethnic/religious minorities ($-.48$), and providing aid to the poor ($-.43$; see Pratto et al., 2013). It is perhaps unsurprising that SDO scales correlate more strongly with intergroup measures since both measure group-based concepts. In fact, this demonstrates that the SDO–environmentalism relation is more notable because there is no obvious content overlap. We also note that Pratto et al. (1994) observed stronger correlations ($-.38$ across three samples) between SDO and environmental policies in U.S. samples, including items such as “Drilling for oil off the California coast,” “Government-mandated recycling programs,” “Taxing environmental polluters to pay for superfund clean ups,” whereas the relationships we identified for U.S. samples were weaker. This comparison suggests that the strength of the associations between SDO and environmentalism is stronger for more specific (and policy-based) measures, which could be explored in future studies.

It is also worth noting that although negative correlations were observed in most samples and measures, nontrivial positive correlations between SSDO and the environmental citizenship measure were observed in both Ghana and the United States (student samples) and in China (community sample). Inspection of the correlations for individual items showed that the positive correlations were mainly driven by a single SSDO item (i.e., “Superior groups should dominate inferior groups”) in relation to more public behaviors in the environmental citizenship measure (e.g., “Write a letter or call your member of Parliament or another government official to support environmental protection,” “Write to newspaper in support of protecting the environment,” “Join public demonstrations or protests supporting environmental protection”). A speculative interpretation is that some who are convinced about the reality of climate change feel the need to take a superior group position to dominate an inferior group (those unconvinced climate change is real) by engaging in more public environmental

citizenship actions. Regardless of the explanation, this finding suggests a differential impact of SDO in relation to more visible environmental citizenship actions, which should be investigated in future research.

Moderators of the SDO–Environmentalism Relation

Besides confirming a negative association between SDO and environmentalism, we also examined whether the strength of this association would differ depending on societal contexts. Comparing the meta-analytical results for each of the environmentalism measures, we observed that only the association between SSDO and the intention to donate to a pro-environmental organization was uniform: High-SDO individuals were less likely to donate to an environmental organization compared to low-SDO individuals, and this finding did not vary across sample type and countries in our study. This indicates that the impact of SDO will likely be uniform for simpler environmentalism measures that do not vary much in content or for measures indexing behaviors that are afforded similarly across cultural contexts.

Notably and supporting our predictions, the levels of inequality, achievement in key dimensions of human development, and performance on environmental issues in a given nation were shown to reinforce individuals' views of human dominance over nature. Pratto et al. (2013) noted that “[t]he more group power differentiation is made salient, the more people apply their orientation toward group inequality to their attitudes” (p. 593). Relating their observation to the environmental domain and our findings, the more group power differentiation is salient via societal inequality, lack of societal development and environmental standards, the more individuals who favor group inequality will tend to exploit the environment. This suggests that the social context of inequality, lack of societal development and environmental standards gives people who endorse social inequality themselves a stronger basis for not engaging in pro-environmental behaviors. Conversely, the *lower* participants' SSDO, the *more* they endorsed pro-environmental actions, and this association is stronger in societies that are more equal and with better environmental performance, and especially stronger in societies with better records on life expectancy, educational attainment, and per capita income. Our findings also provide further evidence for the interplay between individual psychological orientations and sociocultural context (see, e.g., Fischer, Milfont, & Gouveia, 2011; Milfont & Markowitz, 2016; Milfont & Schultz, 2016; Kunst, Fischer, Sidanius, & Thomsen, 2017; Pratto et al., 2013).

Concluding Remarks

Our findings confirm that those who endorse social hierarchy and inequality are less likely to act on environmental issues but that the strength of this association is affected by the societal context in which people live. Factors that curtail the strength of this relationship include living in a more equal, wealthier, and environmentally oriented society. These factors could thus

ameliorate the pervading belief in human dominance over nature. However, our findings are correlational, and thus suggest rather than demonstrate a causal link. If it is true that culture can influence pro-environmental behaviors, then it places even more importance on efforts to address social issues like inequality and development around the world because these efforts will not only address social concerns, but reduce barriers to addressing environmental issues as well—these issues are interconnected as illustrated by the United Nations' Sustainable Development Goals.

Supplemental Material

The supplemental material is available in the online version of the article.

Notes

1. We also note that the meta-analytical results in Tables 2 and 3 extend evidence for the validity of the SSDO scale by showing that overall men have higher levels of social dominance orientation than women, which confirms previous findings (e.g., Lee et al., 2011; Sidanius & Pratto, 1999).
2. Spearman's rank-order correlations showed the Gini index to be negatively associated with both Human Development Index and Environmental Performance Index ($-.65, p < .001$ and $-.54, p < .01$, respectively), which are in turn positively associated ($.58, p < .01$; $N = 25$ for both).

Author Biographies

Taciano L. Milfont is interested in the contributions psychology can make to the science of human-environment interactions. He is Deputy Director of the Centre for Applied Cross-Cultural Research at Victoria University of Wellington, New Zealand and Senior Associate Editor of *Environment and Behavior*. He received the 2013 GV Goddard Early Career Award from the New Zealand Psychological Society for achievement and excellence in research and scholarship.

Paul G. Bain conducts research in social and cross-cultural psychology, with a particular interest in social change and sustainability. Paul is an Associate Editor of the *Asian Journal of Social Psychology*, and an Executive Member of the International Association for Cross-Cultural Psychology.

Yoshihisa Kashima's research focuses on cultural dynamics – the formation, maintenance, and transformation of culture over time, with particular emphasis on culture of sustainability. His writing has appeared in *Psychological Review*, *Psychological Bulletin*, *Journal of Personality and Social Psychology*, *Science*, and *Nature Climate Change*. He was an Associate Editor of the *Journal of Personality and Social Psychology*, and the President of the International Association for Cross-Cultural Psychology.

Victor Corral-Verdugo is Professor of psychology at the University of Sonora, Mexico. He has published numerous books, papers and chapters on environmental psychology topics. His research interests include the study of sustainable behavior and its determinants, the psychological causes and consequences of climate change and the influence of positive environments on human wellbeing, among others.

Carlota Pasquali has a PhD in architecture with master degrees in environmental psychology. She is a Professor at Universidad Simón Bolívar, Venezuela, where she served as Department Head of the Department of Science and Technology of Behavior, and is a member of the research group Vida Urbana y Ambiente (Urban life and Environment).

Lars-Olof Johansson conducts research on environmental attitudes and behavior, decision making, and economic psychology. He is especially interested in distributive justice and how issues of resource management and allocation are linked to policy and public acceptance of policy measures. He is an Associate Professor at the Department of psychology, University of Gothenburg, Sweden.

Yanjun Guan's research interests include cross-cultural psychology and vocational psychology. Yanjun is working as Professor in management at the Durham University Business School, UK.

Valdiney V. Gouveia is Professor of psychology at the Federal University of Paraíba, Brazil, and a funded researcher by the National Council for Scientific and Technological Development. With 16 authored/edited books and over 200 articles, he developed the Functional Theory of Human Values and investigates applications of the psychology of human values to understanding and solving social and environmental issues. His latest books are *Functional Theory of Human Values* (Casa do Psicólogo, 2013) and *Functional Theory of Human Values: Areas of Study and Applications* (Vetor, 2016).

Ragna B. Garðarsdóttir is an Associate Professor of social psychology at the University of Iceland, Reykjavik. Her research focuses on the determinants and various ills of consumer-culture, including environmental impact of consumer behavior.

Guy Doron is an Associate Professor and Senior Lecturer at the Baruch Ivcher School of Psychology Interdisciplinary Center (IDC) Herzliya, Israel. He is the Founding Director of the Relationship Obsessive Compulsive Disorder Research Unit (ROCD.net) and an Associate Editor of *JMIR Mental Health*. His research interests

include cross-cultural investigations of mental health and well-being related processes, obsessive compulsive disorder and mHealth.

Michał Bilewicz is an Associate Professor of psychology at the University of Warsaw, where he chairs the Center for Research on Prejudice. He studies social psychology intergroup relations and political psychology.

Akira Utsugi is an Associate Professor of linguistics at Nagoya University, Japan. He is interested in languages and cultures of Japan and Korea.

Juan Ignacio Aragonés is Professor of social psychology at the Complutense University of Madrid and Associate Editor of *Psycology*. His research focuses on various topics related to environmental psychology, and at present centers on the concept of nature and its relationship with wellbeing, perception of risk, and residential environment. He is the current President of the Environmental Psychology Association (PSICAMB).

Linda Steg is Professor of environmental psychology at the Faculty of Social and Behavioural Sciences, University of Groningen. Her research focuses on understanding factors influencing sustainable behaviour, the effects and acceptability of strategies aimed to encourage pro-environmental behaviour, and how and why acting sustainably affects wellbeing. She is member of the Royal Netherlands Academy of Arts and Sciences, and coordinates the Platform for Energy Research in the Socio-Economic Nexus (PERSON; person.eu). She was scientific director of the Kurt Lewin Institute, and president of Division 4 'Environmental Psychology' of the International Association of Applied Psychology.

Martin Soland, social psychologist, received his PhD at the University of Zurich in 2013. Currently, he is Senior Researcher at the School of Applied Psychology FHNW in Olten, Switzerland. With his research on technology acceptance in the energy sector, he aims at reconciling the needs of corporate stakeholders and private consumers.

Joonha Park is an Assistant Professor of psychology at the Department of Management, Nagoya University of Commerce and Business. She is interested in interactions between culture and various aspects of psychology such as self-construals, values and emotional experiences with a special focus on within-cultural variances in East Asia.

Siegmar Otto is interested in human-environment and human-technology interaction, ecological behavior, data science, and organizational psychology. He is Visiting Professor at the Division of Business and Organizational Psychology, University of Hohenheim, Stuttgart, Germany and a researcher at the Institute of Psychology, Otto-von-Guericke University, Magdeburg, Germany.

Christophe Demarque is an Assistant Professor of social, work and organizational psychology at the University of Aix-Marseille, France. His research focuses on time perspective, decision making and motivation in the field of "green behaviors", but also on the links between time perspective and unstable work. He is the current President of the French Association of Environmental Psychology (ARPENV).

Claire Wagner works in the field of environmental psychology as an Associate Professor in the Department of Psychology at the University of Pretoria, South Africa. She is especially interested in pro-environmental behavior and environmental justice. Currently her research focuses on recycling behavior, water sensitive urban design, and strengthening relations between residents and waste pickers for the development of national guidelines.

Ole Jacob Madsen is interested in the interactions between the individual and society and the environment. He is Associate Professor at the Department of Psychology at the University of Oslo, Norway. His latest book is *Optimizing the Self: Social Representations of Self-help* (Routledge, 2015).

Nadezhda Lebedeva is Professor in the Department of Psychology and Head of the International Laboratory for Socio-cultural Research at the National Research University Higher School of Economics in Moscow, Russia. Her research interests are values, identity, intercultural relations, acculturation, creativity and innovations, social and cultural change. She is the author/editor of 26 books and over 250 articles on social and cross-cultural psychology.

Roberto González is Professor of psychology at P. Universidad Católica de Chile. His research agenda focuses on the study of intergroup relations, acculturation processes, social movements, and reparation associated to political and ethnic conflicts. He serves in several editorial committees of international journals. He is currently a Principal Investigator of the Center for Social Conflict and Cohesion Studies and Associated Researcher at the Center for Intercultural and Indigenous Research.

P. Wesley Schultz is Professor of psychology at California State University, San Marcos, USA. His research focuses on social psychology, and applications of psychological science to environmental sustainability and conservation behavior. Recent studies have examined energy and water conservation, social norms, recycling, litter prevention, and climate change education.

José L. Saiz is Professor of psychology at Universidad de La Frontera, Chile. His current research interests focus on the study of intergroup bias, acculturation, personality, and psychological measurement, mainly from a cultural or cross-cultural perspective.

Tim Kurz is a Senior Lecturer at the University of Bath in the United Kingdom whose research interests lie at the intersections of social, environmental and discursive psychology. He has a particular interest in the ways in which morality surrounding environmental issues is produced via mechanisms of public policy and is negotiated at the level of interpersonal interaction within social networks.

Robert Gifford is Professor of psychology and environmental studies at the University of Victoria, Canada. He is the recipient of career awards from the Environmental Design Research Association and Division 34 of the American Psychological Association, and for International Advancement of Psychology from the Canadian Psychological Association. Professor Gifford is the author of over 135 refereed publications and book chapters, five editions of *Environmental Psychology: Principles and Practice*, and edited *Research Methods for Environmental Psychology* (Wiley, 2016). He was the editor of the *Journal of Environmental Psychology* for 15 years, and served as President of the Environmental Psychology division of the International Association of Applied Psychology.

Charity S. Akotia is an Associate Professor at the Department of Psychology and Dean of the School of Social Sciences, University of Ghana, Legon. She is a social/community psychologist who researches social issues, mental health (in particular, suicidal behavior) and gender issues, including violence among women in Ghana. She has published widely in several local and international journals and has presented papers at conferences worldwide, including keynote addresses. She is a Co-Founder of the Centre for Suicide and Violence Research.

Nína M. Saviolidis is a PhD candidate at the School of Business at the University of Iceland. She has an interdisciplinary background with an undergraduate degree in psychology and a master's degree in the Environment and Natural Resources program from the same university. Her research interests include sustainability indicators, environmental policy making, pro-environmental behavior, and organizational change.

Gró Einarsdóttir is a PhD candidate in psychology at the University of Gothenburg, Sweden. Her primary research interest is in how to engage people in voluntary climate change action.
